Mitosis is the process that a somatic cell divides into two daughter cells. It is an important process in normal organism development. Meiosis is the type of cell division by which germ cells (eggs and sperm) are produced. Meiosis involves a reduction in the amount of genetic material. Both types of cell division have similar phases: prophase, prometaphase, metaphase, anaphase and telophase.

The "goal" of mitosis is to make sure that each daughter cell gets a perfect, full set of chromosomes. In order for cell division to happen successfully, the cell must be large enough to divide into two and also to contribute sufficient nuclear and cytoplasmic components to each daughter cell. So therefore, before a cell divides, key cellular components are

~~Meiosis And Genetics Study Guide Answers~~

Mitosis is a highly complex process consisting of six distinct sequential stages – prophase, prometaphase, metaphase, anaphase, telophase, and cytokinesis (Figure 2). Mitotic progression is highly regulated and involves dynamic modulation of the actin cytoskeleton, microtubule network (formation of mitotic spindle), as well as membranes to align and then equally segregate the genome and cytoplasmic contents into two daughter cells.
